

The Collected

Art happens in different forms. I am interested in changing forms. I am interested in machine learning.

CONCEPT

Cemeteries are museums that contain humans as datasets. Merging art collections (many containing figures that are dead) allow me to learn stories, techniques, fictions, historical and social elements. A question: How would an AI collection look like or what does it tell us possibly? AI as an intermediary. What medium is a human being? What medium is time? What does it mean to be made of?

01
COLLECT

ARCHIVE ONE

Goldsmiths Textile Collection

Train a dreambooth lora with 1400 textile images. Make the Goldsmiths LoRA look at the Russell-Cotes collection and attempt to mimic its shapes using only yarn and thread.

ARCHIVE TWO

Russell-Cotes Collection

I wrote a batch-processing Python script using Stable Diffusion 1.5 and an IP-Adapter. I fed the script 36 original photographs of the Russell-Cotes collection.

ARCHIVE THREE

Cemetery dataset

My own cemetery images. The video is mainly made from these images, and from WGAN training with them.

36 woven tapestries

To prevent the AI from generating flat photographs, I overdrove the LoRA weights (1.6), cranked the CFG scale (10.5), used a gritty scheduler and wrote text prompts banning photographic elements. A new dataset of 36 highly textured, three-dimensional woven tapestries that matched the structural layout of the Russell-Cotes rooms and sculptures.

02
FUSE

STEP ONE

Paired dataset

A metadata.jsonl map linking the original Russell-Cotes photographs (Condition) to the heavy weave generations (Target), bridged by the instruction: transform this scene into a heavy goldsmiths textile tapestry.

STEP TWO

Model merging

Mixing the weights is the final step where I permanently fuse my two models together into one. The two archives are permanently fused into a single, inseparable new entity.

03
EMBODY

TWO DIMENSIONS

Heatpress and UV

2d heatpress print on latex and uv print on leather. The wall will have the uv prints on a recycled pla surface (colourful).

THREE DIMENSIONS

Mesh and resin

Transform a generated image into 3D mesh and then print it. I made a clear resin 3D print as the main sculpture.

04
RELEASE

MOVEMENT

World model

I have trained my 3d print called collected in a car racing model in mujoco, using world model.

PLACE

Environment

I have used threejs to create an environment for the collected, mostly AI and touchdesigner custom visuals used.

MOVING IMAGE AND SOUND

Cemetery video

The gravestones are playing a game like chess with their stone. Stones slowly come to life and walk. I used the green generated video's still for the sound.

INSTALLATION

Shown in a church, in light. 2 flat surfaces from a tv, one looks like an aluminium, one is a broken screen, laid on the floor. The wall will have the uv prints on a recycled pla surface. Headphones for the sound.

TOOLS

Stable Diffusion 1.5, U-Net, DreamBooth LoRA, IP-Adapter, InstructPix2Pix, WGAN, ComfyUI, Python, PyCharm, MuJoCo, three.js, TouchDesigner.

MATERIALS

Clear resin, recycled PLA, latex, leather, salvaged screen surfaces.
